# Outline

- ① Brief Introduction
- ② traing and test of CNN
- ③ Summary

# traditional methods of PDE evaluation

Calculate the expected p.e by "cut" or "fitting" of charge spectrum.

图: "cut" the charge spectrum to count pedestal events

图: fit using a PMT photon response model

# waveform classification using CNN

CNN can perform a powerful PSD and classify the waveforms, then we could get explicit p.e during one test.

图: tags of typical waveform from CNN

图: classification of events in one test

# the expected photon number

If we do a "cut" is the charge spectrum@0.25 spe, the averager photon number  $\mu$  can be acquired by<sup>1</sup>

$$\mu = -\ln\left(\frac{N_0}{N}\right) \quad (1)$$

where  $N_0$  is the number of pedestal(0 p.e) events,  $N$  is the total event number.

However, if we know explicitly the photon number of specific event, the  $\mu$  value is :

$$\mu = 1 \times n_1 + 2 \times n_2 + \cdots + N \times n_N \quad (2)$$

where  $n_N$  is the number of  $N$  p.e events.

# input of CNN

training data selection:

- random selection from different PMTs(NNVT and HAMAMATSU)
- $1.5 < QDC < 1.7$  for 1p.e
- $3.1 < QDC < 3.3$  for 2p.e
- $4.7 < QDC < 4.9$  for 3p.e

# Output waveforms of PMT @Gain = $10^7$

The 2-D waveform histogram contains all the recorded waveforms, we can clearly see the "delayed signals" of HAMMATSU PMT and "big signals" of NNVN PMTs.

图: all frames of NNVN PMT

# calculation of PDE

we can obtain the average photon number  $\mu_{test}$  from charge spectrum, along with the  $drawer_{factor}^2$ , the PDE result from container system is:

$$PDE_c = \mu_{test} \times drawer_{factor} \quad (3)$$

Then we map the PDE from container to the final PDE value with the help of container  $f_{cs}^3$ :

$$PDE = PDE_c \cdot f_{cs} + constant \quad (4)$$

---

<sup>2</sup>Calibrate the drawer factor using PMT tested in the drawer which has vendor QE value.

<sup>3</sup>linear correlation factor

# statistical results

Mean value of parameters for HAMAMATSU-PMT and NNVT-PMT<sup>4</sup>:

parameters (mean)	HAMAMATSU	NNVT
DCR(kHz)	15.38	41.24
rise time(ns)	7.4	3.2
fall time(ns)	10.36	15.9
PV	3.39	3.19
resolution	0.28	0.35
HV@1E7(V)	1861	1783
FWHM(ns)	9.08	5.8

<sup>4</sup>For the parameter TTS, we need to test the internal time resolution firstly, since we found the TTS results is highly drawer related.

## summary

- the charge and amplitude stability of HAMAMATSU PMT is better.
- $\sim 6k$  NNV T PMTs and  $5k$  HAMAMATSU PMTs has been tested in container system, test results and test reports are available from PMTDataBase<sup>5</sup>.
- we reject or accept one PMT according to its performance test results from container and scanning station.
- we need to study the "delay signal" of HAMAMATSU PMT and "big signal" of NNV T PMT<sup>6</sup> in detail<sup>7</sup>.
- the expected mean PDE value is 30.4% and mean DCR value is  $\sim 34kHz$ <sup>8</sup> in CD.

---

<sup>5</sup> [pmtddb.juno.ihep.ac.cn](http://pmtddb.juno.ihep.ac.cn)

<sup>6</sup> especially when PMT working in the multi-photon case

<sup>7</sup> one option is to transport several PMTs to SYSU for detailed study

<sup>8</sup> will decrease after installation
