Outline

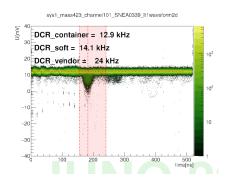

Brief Introduction

2 traing and test of CNN

Summary

the "big signals" of MCP PMT

The typical waveforms ¹ of MCP PMT, compared with dynode PMT.

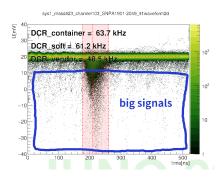

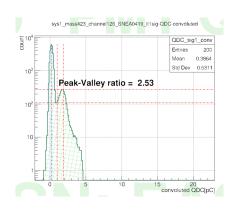

图: waveforms of HAMAMATSU PMT

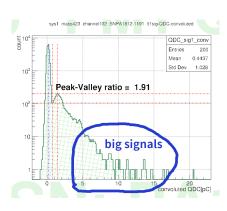

■: waveforms of MCP PMT

¹gain= 1E7, $\mu \simeq 0.1$

the "big signals" of MCP PMT

The "long tail" in charge spectrum² of MCP PMT, compared with dynode PMT.

SPE of HAMAMATSU PMT

SPE of MCP PMT

 $^{^{2}}$ gain= 1E7, $\mu \simeq 0.1$

Based on the container testing data, we can acquire wavefroms of the MCP PMT in 5 different illumination levels:

- 1 dark noise mode [no light incident]
- 2 non-trigger window @1 p.e
- $3 \mu \simeq 0.1 \text{ p.e}$
- \bullet $\mu \simeq 1$ p.e
- **5** $\mu = \text{multi-p.e} [\text{by laser}]$

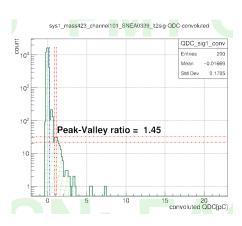

case 1:[dark noise]

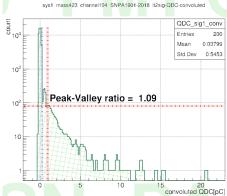

The typical waveform and charge spectrum of MCP PMT@gain = 10^7 . If we suppose all the dark counts is caused by single thermal electron, then those fake multi-p.e events are caused by the magnification of MCP.

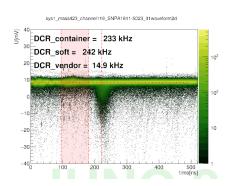

case 1:[dark noise]

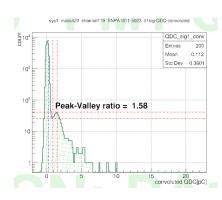

The typical charge spectrum of HAMAMATSU and MCP PMT@gain = 10^7 .

select the time interval before "trigger window",we can see similar QDC spectrum with dark noise case.

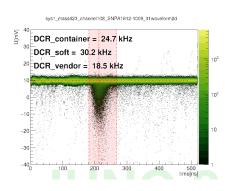

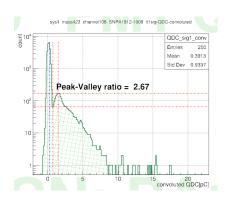

photon response characters of MCP PMT @ $\mu \simeq 0.1$

case 3: $\mu \simeq 0.1$

In the trigger window, we can still see those "big signals" with charge >3p.e.

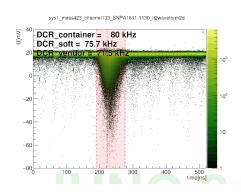

\blacksquare: waeforms @ $\mu \simeq 0.1$

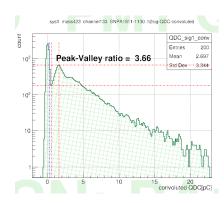

3: QDC @ $\mu \simeq 0.1$

photon response characters of MCP PMT @ $\mu \simeq 1$

case 4: $\mu \simeq 1$

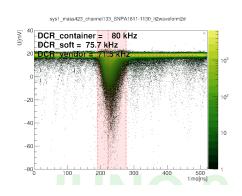

When the light intensity increase to $\mu \simeq 1$ we can see a continuous "long tail" with charge >5p.e; this is a clear clue that MCP will magnify little part of electrons with abnornal large gain.

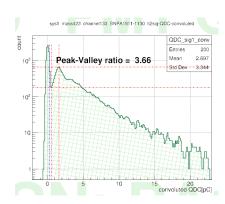

case 5: $\mu > 2p.e$.

When the light intensity increase to $\mu \simeq 1$ we can see a continuous "long tail" with charge >5p.e; this is a clear clue that MCP will magnify little part of electrons with abnornal large gain.

number

To conclude the above information, we find:

• The Gain of MCP-PMT is not stable enough, It has small propobilty to magnify single p.e to unreasonable large charge.

the expected photon number

If we do a "cut" is the charge spectrum@0.25 spe, the averager photon number μ can be acquired by³

$$\mu = -\ln(\frac{N_0}{N})\tag{1}$$

where N_0 is the number of pedestal (0 p.e) events, N is the total event number.

However, if we know explicitly the photon number of specific event, the μ value is :

$$\mu = 1 \times \mathbf{n}_1 + 2 \times \mathbf{n}_2 + \dots + \mathbf{N} \times \mathbf{n}_{\mathbf{N}} \tag{2}$$

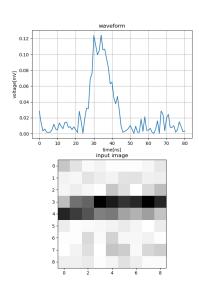

where n_N is the number of N p.e events.

input of CNN

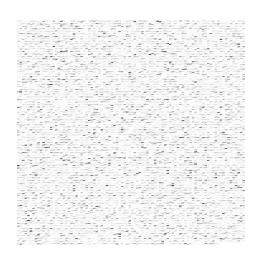

training data slecetion and pre-process:

- random selection from different PMTs
- 1.5<QDC<1.7 for 1p.e
- 3.1<QDC<3.3 for 2p.e
- 4.7<QDC<4.9 for 3p.e
- 81ns ROI \rightarrow 9×9 2D image
- normalization

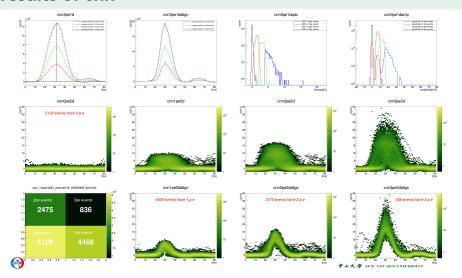

CNN parameters

- 30k training waveform samples
- 2 convolution layers
- 4 output tags
- accuracy $\simeq 0.95$

: input data

results of cnn

: HAMAMATSU PMT

results of cnn

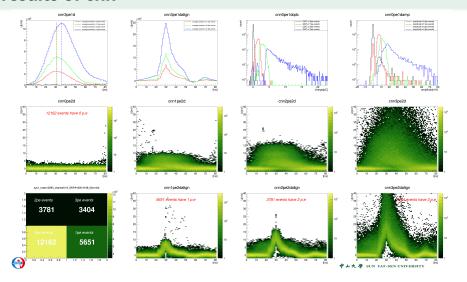

图: NNVT PMT

summary

- PSD by CNN provide a new option for PDE evaluation.
- can achieve sim0.95 acuuracy with the traditional method using simple NN.
- much faster than tradition methods in PDE evaluation.
- CNN can ectract more infromation from waveforms.

to list:

- refine the training samples and network structure.
- compare the accuracy in more details, for example using the reference tubes in container system.
- improve the input data quality.
